# Lecture 10: Trace and Replay of Task Parallel Programs

Vivek Kumar
Computer Science and Engineering
IIIT Delhi
vivekk@iiitd.ac.in

#### Last Lecture (Recap)

#### **Today's Class**

Trace and replay of asynchronous tasks

- It is a technique for understanding the behavior of the parallel runtime / program during the execution
  - High-level details
    - Total number of tasks created
    - Total number of tasks stolen.
    - Total number of tasks migrated across NUMA domains
    - Total number of failed steals
    - Task execution time, etc.
  - Low-level details
    - Tracing the program execution (computation graph)
    - Computation type (compute-bound / memory-bound)
    - Power usage
    - Instructions retired for each task
    - Total CPU stalls, etc.

It is a technique for understanding the behavior of the parallel runtime / program during the execution

Easily obtained using

thread local counters

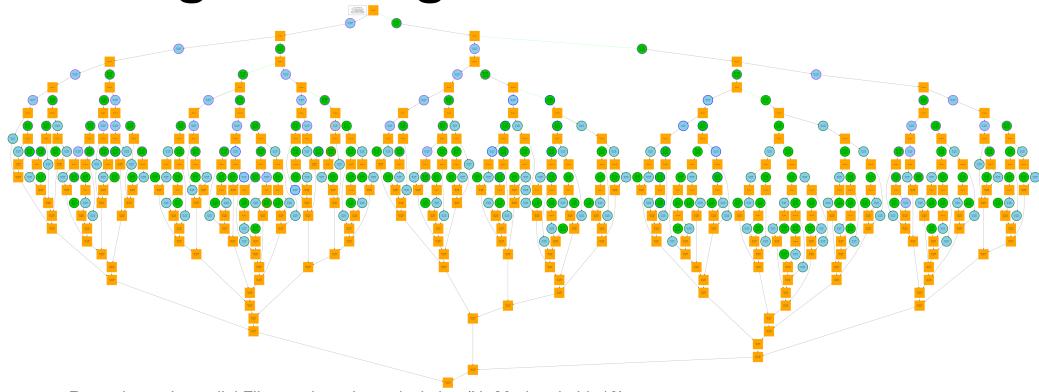

- High-level details
  - Total number of tasks created
  - Total number of tasks stolen.
  - Total number of tasks migrated across NUMA domains
  - Total number of failed steals
  - Task execution time, etc.
- I ow-level details
  - Tracing the program execution (computation graph)
  - Computation type (compute-bound / memory-bound)
  - Power usage
  - Instructions retired for each task
  - Total CPU stalls, etc.

Requires special support

- It is a technique for understanding the behavior of the parallel runtime / program during the execution
  - High-level details
    - Total number of tasks created
    - Total number of tasks stolen
    - Total number of tasks migrated across NUMA domains
    - Total number of failed steals
    - Task execution time, etc.
  - Low-level details
    - Tracing the program execution (computation graph)
    - Computation type (compute-bound / memory-bound)
    - Power usage
    - Instructions retired for each task
    - Total CPU stalls, etc.

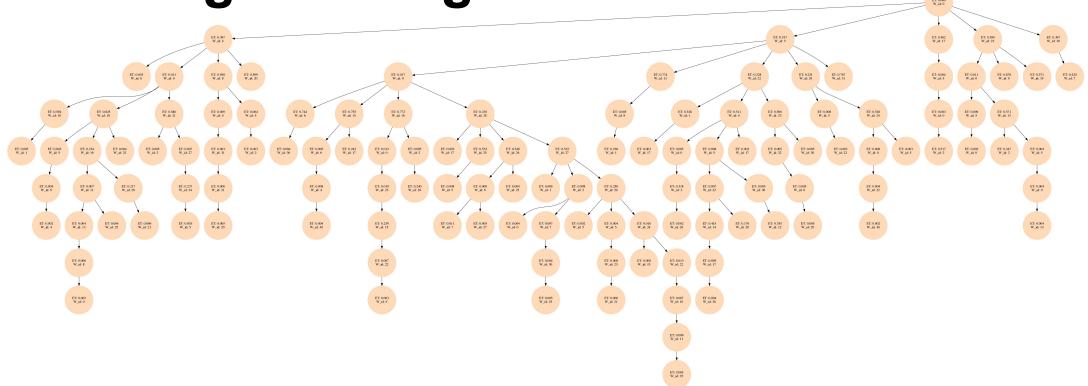

- Recursive task parallel Fibonacci number calculation (N=20, threshold=10)
  - o Graph will be too big to fit in the slide for large N, hence small value chosen
- Blue node represents fib(n-2), green node represents async fib(n-1), and orange rectangular boxes are the synchronization scope for tasks created in that scope

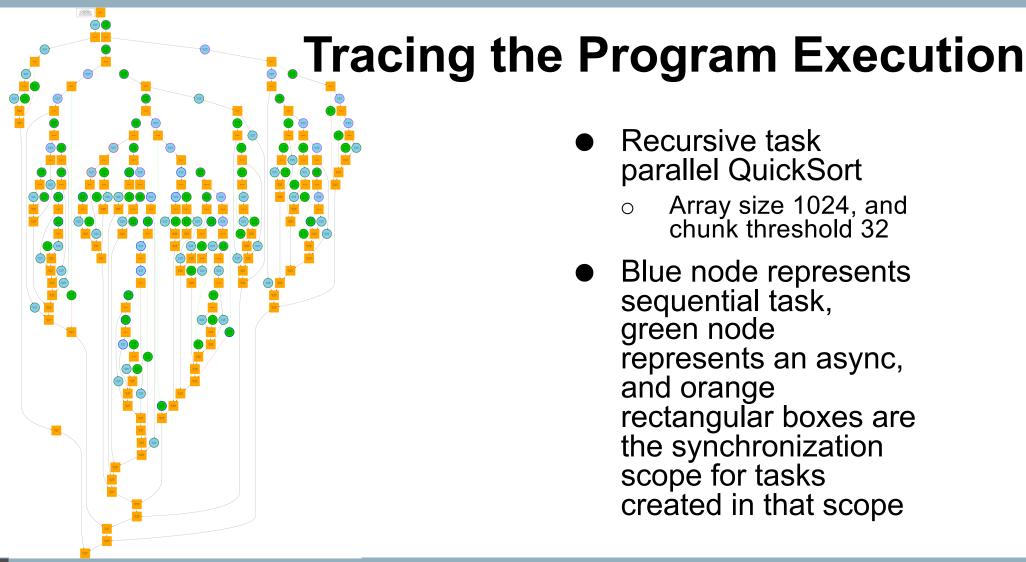

Enlarging the nodes from the computation

- ET=Execution
- WT: Wait time
  - WC id: Id of worker who created this task
  - WE id: Id of the worker who executed this task (due to

Steal tree of the same Fibonacci execution using 32 workers

- Recursive task parallel QuickSort
  - Array size 1024, and chunk threshold 32
- Blue node represents sequential task, green node represents an async, and orange rectangular boxes are the synchronization scope for tasks created in that scope

- Advantages
  - Offline analysis can help in reducing/increasing the task threshold if its not done automatically by the runtime
  - Reducing task management overheads in iterative applications
    - How?

**Iterative Averaging** 

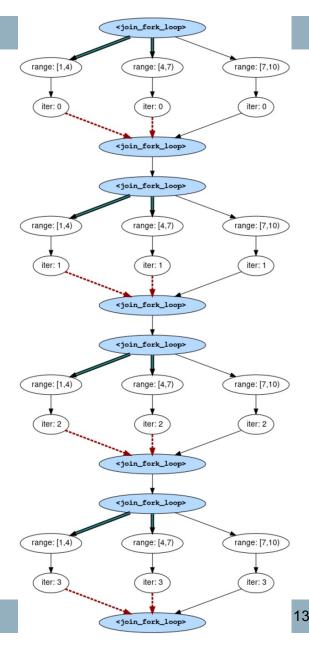

```
double A[SIZE+2], A shadow[SIZE+2];
void recurse(int low, int high) {
  if((high - low) > THRESHOLD) {
    int mid = (high+low)/2;
    finish ([=](){
      async([=](){ recurse(low, mid); });
      recurse(mid, high);
    });
  } else {
    for(int j=low; j<high; j++) {</pre>
      A shadow[j] = (A[j-1] + A[j+1])/2.0;
void compute(int MAX ITERS) {
  for(int i=0; i<MAX ITERS; i++) {</pre>
    recurse(1, SIZE+1);
    double* temp = A shadow;
    A \text{ shadow} = A;
    A = temp;
```

- Initialize a one-dimensional array of (SIZE+2) double's with boundary conditions, A[0] = 0 and A[SIZE+1] = 1
- In each iteration, each interior element A[j] in 1...SIZE is replaced by the average of its left and right neighbours
  - Two separate arrays are used in each iteration, one for old values and the other for the new values
- After a sufficient number of iterations, we expect each element of the array to converge to A[j] = (A[j-1]+A[j+1])/2, for all j in 1...SIZE

Details: https://classes.engineering.wustl.edu/cse231/core/index.php/lterative\_Averaging

### **Iterative Averaging**

- Observations
  - Exact same computation graph in each for loop iteration in compute()
- Optimization
  - Improved locality if each workers executes the exact same set of tasks in each for loop iteration of compute
  - Random work-stealing
    - It would result in poor locality as each worker could get different set of tasks in each for loop iteration of compute
  - Trace/Replay for improving locality
    - Trace (i.e., record) the tasks executed by each worker during the first iteration of for loop inside compute
    - For the rest of iterations of the above for loop of compute, disable random work-stealing and use the information gathered during the Trace (i.e., record) phase to replay the exact set of tasks at each worker

Details: https://classes.engineering.wustl.edu/cse231/core/index.php/Iterative\_Averaging

#### Advantages

- Offline analysis can help in reducing/increasing the task threshold if its not done automatically by the runtime
- Reducing task management overheads in iterative applications
  - How?
- Data-race detection
  - If there is NO path to connect between two nodes (i.e., they may execute in parallel), and if they perform read/write or write/write operation on a shared memory location then it's a data race

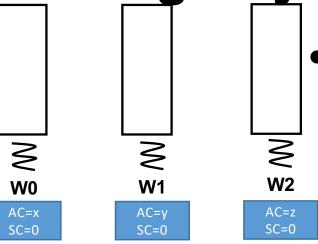

- Advantages
  - o Offline analysis can help in reducing/increasing the task threshold if its not done automatically by the runtime
  - Reducing task management overheads in iterative applications
    - How?
  - Data-race detection
    - If there is NO path to connect between two nodes (i.e., they may execute in parallel), and if they perform read/write or write/write shared memory location then it's a data race

      Overheads?

#### Drawbacks

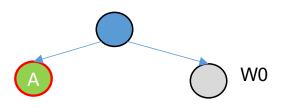

- Recording details for each and every task will consume too much memory (e.g., millions of tasks in Fibonacci 40)
- Profiling overheads as each worker has to do some extra work

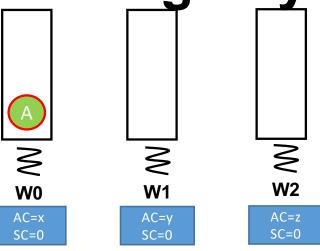

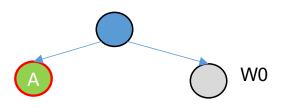

Let there be three workers in a work-stealing based parallel runtime

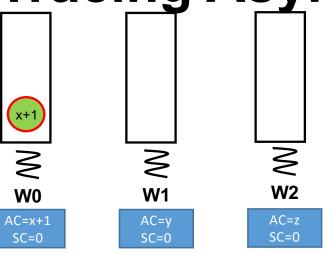

- Worker encountering an async will push that task into its deque, and would start working on the statement after the async
- Each worker has two counters
  - Async Counter (AC)
    - Each worker initializes its AC value = workerID \* INT\_MAX/numWork ers
    - To assign a unique id to each async
  - Steal Counter (SC)
    - Initialized to zero

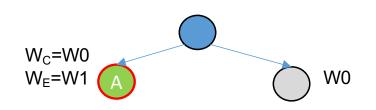

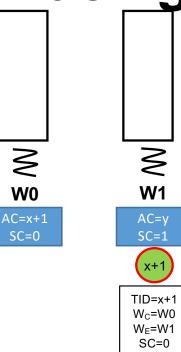

- Worker W0
   starts a
   recursive
   task parallel
   application
- W0 creates an async A that is pushed into its deque

AC at W0 is incremented and is assigned as the ID of the Task A before its pushed into W0's deque

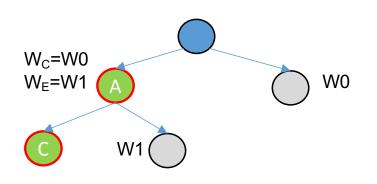

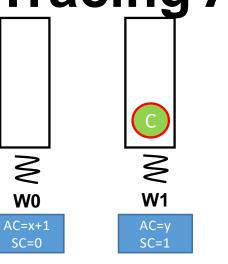

**W2** 

AC=z

SC=0

- W1 steals the task A from W0
  - It appends a node in a private linked list containing info about this stolen task A
    - o ID of the task (TID=x+1)
    - Worker who created this task (W<sub>C</sub>=W0)
    - Worker who executed (stolen) this async (W<sub>E</sub>=W1)
    - Current Steal Counter at W1 (SC=0)
- W1 then increment its Steal Counter (SC) before executing this stolen task

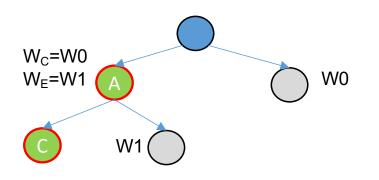

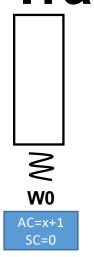

W1 creates an async C

 $\begin{array}{c} \text{TID=x+1} \\ \text{W}_{\text{C}}\text{=W0} \\ \text{W}_{\text{E}}\text{=W1} \\ \text{SC=0} \end{array}$ 

**W2** 

AC=z SC=0

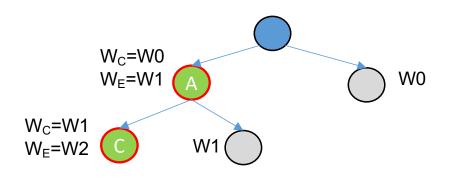

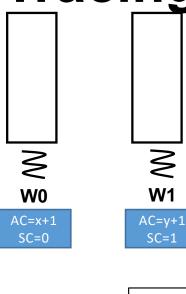

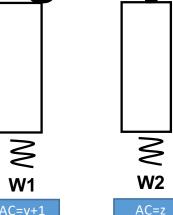

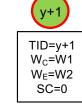

AC at W1 is incremented and is assigned as the ID of the Task C
 before its pushed into W1's deque

TID=y+3 **W**c=W1 W<sub>E</sub>=W2 SC=2

- Recursive task parallel computation has now completed
- W0 now iterates over the linked list stored at each worker
  - W0 aggregates each of the linked list nodes based on the worker who actually created the task corresponding to that node (value of W<sub>C</sub>)
    - Hence, there would be numWorker number of linked lists
    - Each worker would finally have nodes with W<sub>c</sub> value corresponding to itself

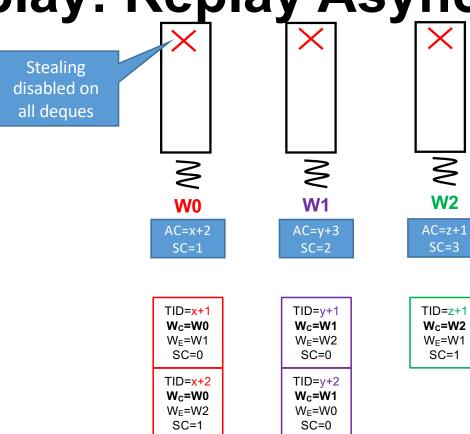

Trace & Replay: List Aggregation

**Trace & Replay: List Sorting** 

W0 will sort each of these lists (at each worker) based on the TID stored inside the nodes

Replay phase is essentially executing the same recursive task parallel program, but by using the steal information stored at each worker during the tracing phase

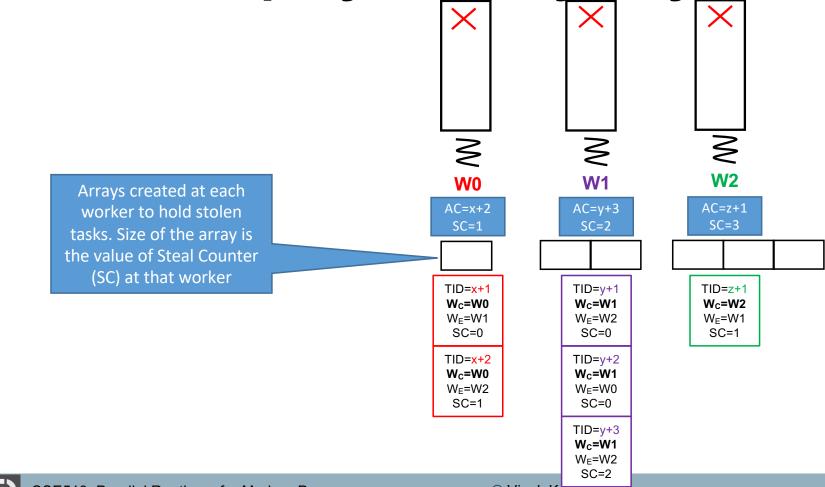

SC=3

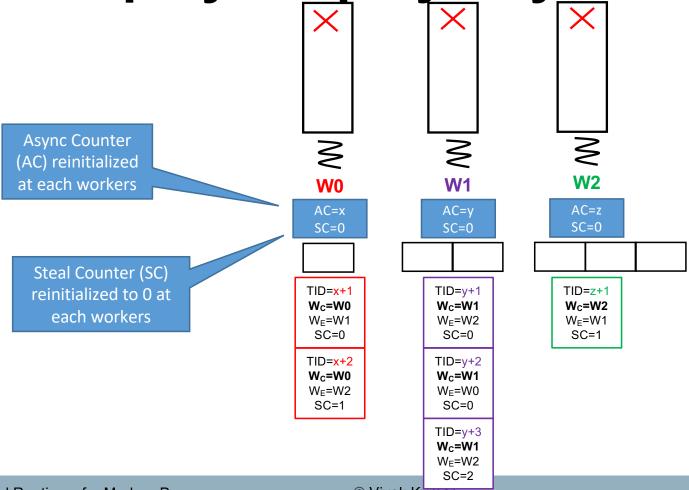

SC=1

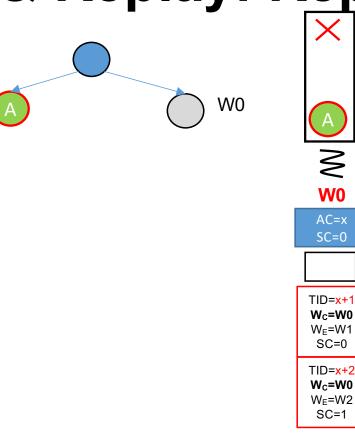

During the replay phase, each worker would disable the direct steal operation on its deque

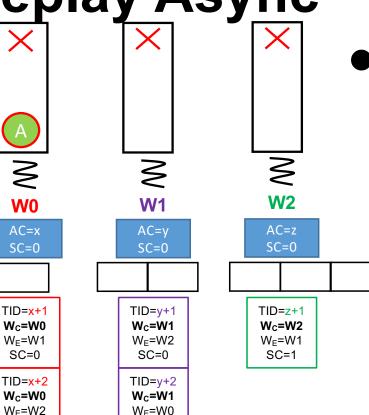

TID=v+3

W<sub>C</sub>=W1 W<sub>E</sub>=W2 SC=2

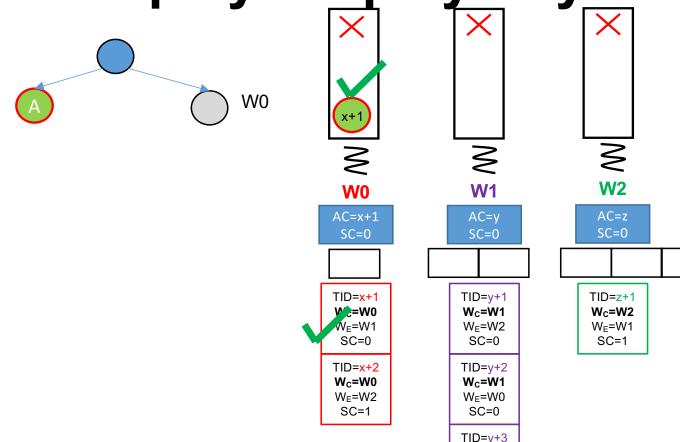

W0 starts
the
computation
and creates
an async A

SC=0

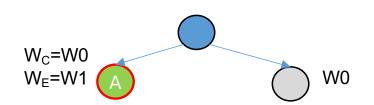

TID=y+3 **W**c=W1 W<sub>E</sub>=W2 SC=2

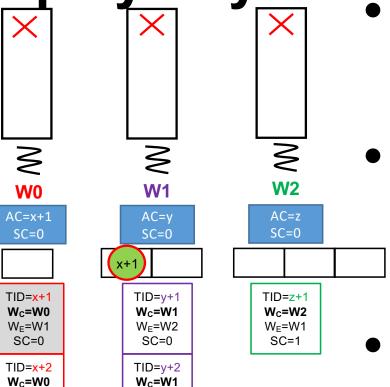

AC at W0 is incremented and is assigned as the ID of the Task A **before** its pushed into W0's deque

When W0 attempts to push task A into its deque, it would observe that the TID of A matches with the currently active steal node on its linked list

W<sub>c</sub>=W1 W<sub>E</sub>=W2 SC=2

W0 does not push task A into its deque, but directly copies it into the array at W1

A is copied into an index value corresponding to SC counter stored inside the steal info node of task A at W0 (i.e., 0)

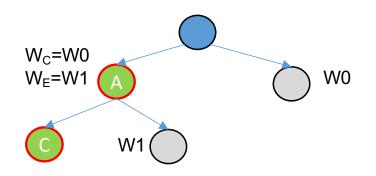

W0 remove the currently pointing steal node from its linked list

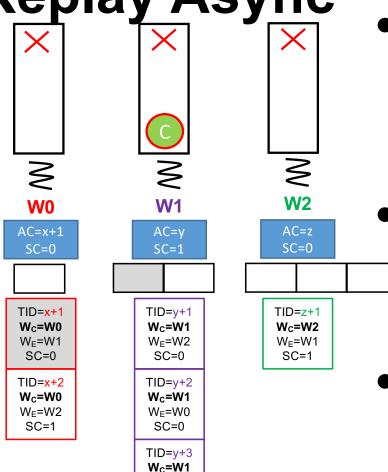

W<sub>E</sub>=W0 SC=0

TID=y+3 **W**c=W1 W<sub>E</sub>=W2 SC=2

W<sub>F</sub>=W2

SC=1

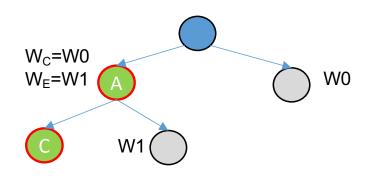

W<sub>E</sub>=W2 SC=2

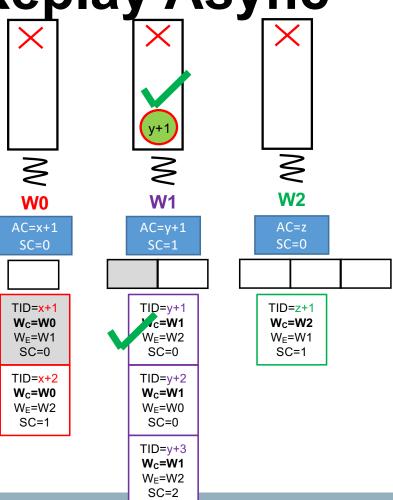

© Vivek Kumar

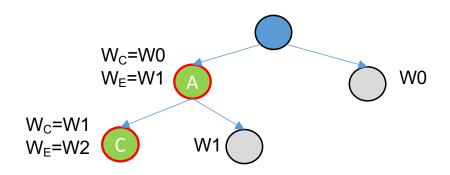

Until now, W1 was waiting for a task to be available in its task array at an index of its current SC value (i.e., 0)

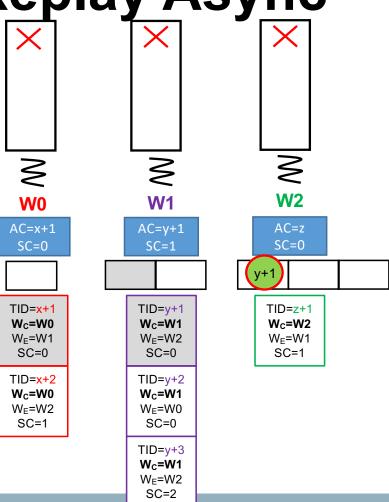

After receiving the task, W1 will increment its SC value and will start executing the transferred task

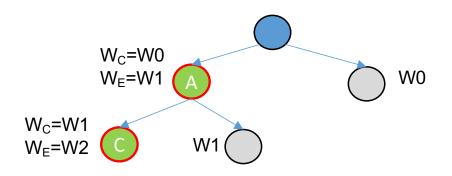

W1 generates an async C once it starts the execution of the transferred task
